Abstract

Integration of seismic refraction tomography and multi-channel analyses shear wave methods were used at Al al-Bayt university campus in Mafrq, NE Jordan to delineate the shallow subsurface layering and determine their geotechnical properties, in addition, to estimate the geotechnical engineering parameters of the superficial deposits for detailed purposes. The P-wave refraction velocities were found to range from 180 to 2300 m/s for the three identified layers which indicating superficial soil deposits with an increasing degree of compaction with depth. The S-wave velocities were found to lie in a narrow velocity range (250 to 600 m/s), which badly resolved the subsurface layering. Moreover, four soil samples were taken from the sites of seismic survey points for density calculations. The average calculated density was found to be 1.85 g/cm³. Two soil samples from nearby seismic profile-1 and seismic profile-4 were tested for geotechnical properties. The results showed that the seismic method is an effective tool to estimate the different elastic moduli; Poisson's ratio, Young's modulus, Bulk modulus, Shear modulus, Lamé's constants, and geotechnical engineering parameters; N-value, bearing capacity, material index, concentration index, and stress ratio of the superficial soil deposits. The study recommends conducting a detailed geophysical study before starting any type of geoengineering construction in the area.

Keywords: Elastic moduli; Geotechnical parameters; Multi-channel analyses shear wave; seismic refraction tomography; superficial deposits

1. Introduction

Several geophysical methods have been suggested for engineering site studies, it was considered as progressively acceptable tools to give more information about the subsurface structures and lithology for seismologists and civil engineers (Benson and Yuhr, 2002; Goldstein, 1994; Benson et al. 1983; Al-Kubaisi and Shakir, 2018; Alsamarraie, 2020). The seismic methods are traditionally used in several exploration studies such as civil engineering and geotechnical studies to investigate the subsurface geological layering and many other purposes such as environmental, engineering, groundwater, industrial-mineral exploration, and hydrocarbon exploration (Khalil and Hanafy, 2008; Bridle, 2006; Hodgkinson and Brown, 2005). The seismic methods are attractive because of their cost-effectiveness, fast field surveying and easy data processing and interpretation. The seismic refraction tomography (SRT) method is commonly used to detect the physical properties of the subsurface in order to mapping the horizontal and vertical variations of subsurface geological features and soil characterization in the site investigations (Al-Heety and Shanshal, 2016). The Multichannel-Analyses

DOI: [10.46717/igi.54.1D.2Ms-2021-04-22](https://doi.org/10.46717/igi.54.1D.2Ms-2021-04-22)

Shear Wave (MASW) method is used in geotechnical studies to estimate shear velocity (V_s) of subsurface materials, the relation between (V_s) and depth, and other geotechnical parameters of soil. It is used commonly for shallow depths (Priya and Dodagoudar, 2017; Park, 2013). Several geophysical studies have been carried out to determine the layers of various seismic velocities and estimate engineering parameters in different parts of the world by seismic methods (Abudeif et al. 2019; Srinivas et al. 2018; Al-Heety and Shanshal, 2016; Pegah and Liu, 2016; Al-Saigh and Al-Heety, 2013).

This study aims to investigate the subsurface geological layering and estimate the engineering parameters of the soil, it will enable us to determine if the various seismic techniques are efficient tools to describe near surface and superficial soil deposits. Moreover, it will also help us to estimate the different dynamic elastic properties of the soil layer which would be used for future engineering construction.

2. Study Area

Al-Bayt University campus is located in Al-Mafraq, NE-Jordan, it is bounded by 239119 - 240402 E and 3580967-3579482 N, (UTM coordinate system) (Fig. 1). The study area covers an area of about 2.68 km² which is characterized by its relatively flat topography (Al-Ansari and Baban, 2001). Geologically, the Quaternary deposits are represented by superficial deposits (clayey silty sand) which almost covers Al-Mafraq, and consists mainly of two soil types: the red soil and the desert soil (Smadi, 1997; Gharaibeh, 2003).

Fig. 1. Location map of the study area (Al al-Bayt university campus)

3. Materials and Methods

The adopted methodology to achieve the objectives of the present study is summarized in the flow chart shown in Fig. 2.

Fig. 2. Flow chart displays the adopted methodology used in this study

3.1. Geophysical Survey

3.1.1. Seismic refraction tomography (SRT)

The basic principle of the SRT method is depending on the seismic waves travel times measurements that critically refracted at the different velocities layers (Ayolabi et al. 2009). In the SRT method, the acoustic velocities increasing with depth. The primary wave velocity data presented as cross-section plots representing the P-wave path, velocities, and depths to various velocity layers and analyzing the propagation of seismic primary waves created. The objective is to produce a 2-D primary velocity (V_p) section (Anomohanran, 2013). The objective of the SRT method is to determine the subsurface layers using a velocity of primary wave (V_p) as a 2-D cross-section. The 2D sections (V_p and V_s) display different characteristics, depending on the lithology changes or subsurface properties.

3.1.2. Multichannel analyses shear wave (MASW)

The basic principle of the MASW method is depending on measuring and analyzing the propagation of seismic Rayleigh surface waves created from different seismic sources. (Park et al. 1999). The key parameter of the accuracy of MASW data analyses is the deducing of an accurate dispersion curve. Dispersion curve is a relation between the frequency and the phase velocity as shown in (Fig. 3d) (Olafsdottir et al. 2018). The main objective of the MASW method is to characterize the shallow subsurface layering and to support estimating the fundamental elastic properties of the topsoil layer for civil infrastructure constructions. Fig. 3 summarizes the main steps of processing of MASW data to deduce the 2-D shear wave velocity (V_s) section.

3.1.3. Data acquisition and processing

Nine seismic profiles 60 m long were conducted in this study. Geometrics Smart Seis instrument was used for data collection. The system consists of twelve geophones of 4.5 Hz frequency, vertical geophones. The geophone spacing was 3 m for profiles No. 5 to 9, and 5 m for profiles No. 1 to 4. A 10 kg sledgehammer on a striker plate was used as the source of energy. The data were recorded with a sample interval of 1 millisecond in a time-window of 1024 milliseconds. The analysis of seismic data was done by Seis Imager/SWTM software.

Fig. 3. Summary of main steps of MASW data processing and deducing the 2-D shear velocity (V_s) section (Modified after Olafsdottir et al. 2018)

3.2. Elastic Moduli and Geotechnical Engineering Parameters

3.2.1. Elastic moduli and seismic velocities

The elastic moduli can be calculated using the seismic velocities (Primary velocity (V_p) and Shear velocity (V_s)) obtained by MASW and SRT methods to give a better engineering understanding of the subsurface layers (Khalil and Hanafy, 2016). These moduli are Young's modulus (E), Shear modulus (μ), Bulk modulus (K), Lamé's constant (λ) and Poisson's ratio (σ). Young's modulus (E) and shear modulus (μ) can be determined from defined formulas based on the density (ρ) information (Table 1). The shear wave velocity (V_s) is considered as an important parameter to estimate the elastic moduli, therefore, shear modulus (μ) can be determined fully precisely once shear velocity is known, whereas to calculate the Young's modulus (E) from equations, Poisson's ratio (σ) must be known to obtain a comparable accurate value (Patil et al. 2017). Table 1 lists some of the inter-relationships between different elastic moduli and density of the rocks for homogeneous and isotropic media.

Table 1. Elastic moduli and seismic velocities inter-relationships

Elastic moduli	Used formula	Reference
Young's modulus (E)	$E = 2\rho V_s^2(1 + \sigma)$	(Park, 2013)
Shear modulus (μ)	$\mu = \rho V_s^2$	(Birch, 1961)
Bulk modulus (K)	$K = \rho \left(V_p^2 - \left(\frac{4}{3} \right) V_s^2 \right)$	(Birch, 1961)
Poisson's ratio (σ)	$\sigma = \frac{1}{2} \left[1 - \frac{1}{\left(\frac{V_p}{V_s} \right)^2 - 1} \right]$	(Christensen, 1996)
Lamé' constant (λ)	$\lambda = \rho(V_p^2 - 2V_s^2)$	(Birch, 1961)

3.2.2. Geotechnical engineering parameters and seismic velocities

The geotechnical engineering parameters are estimated depending on the information of soil densities and seismic wave velocities (V_p and V_s) to evaluate the suitability of subsurface construction materials (Abudeif et al. 2019). Table 2 lists the used equations of geotechnical parameters and their inter-relationships.

Table 2. Definitions of geotechnical engineering parameters

Geotechnical engineering parameters	Used formula	Reference
N-value	$V_s = 89.9 * N^{0.341}$	(Stümpel et al., 1984)
Ultimate bearing capacity (Q_{ult})	$Q_{ult} = 30 * N$	(Parry, 1977)
Allowable bearing capacity (Q_a)	$Q_a = Q_{ult} / F^*$	(Parry, 1977)
Concentration index (C_i)	$C_i = (1 + \sigma) / \sigma$	(Bowels, 1982)
Stress ratio (S_i)	$S_i = \sigma / (1 - \sigma)$	(Thomsen, 1986)
Material index (M_i)	$M_i = (1 - 4\sigma)$	(Abd El-Rahman, 1989).
(*) F: factor of safety equal 2 for the cohesionless		

3.2.3. Elastic moduli and geotechnical tests

Table 3 lists some of the inter-relationships between Young's modulus (E) and Bulk modulus (K) of homogeneous isotropic linear elastic materials to calculate Shear modulus (μ), Poisson's ratio (σ) and Lamé' constant (λ) (Birch, 1961), that are used in this study.

Table 3. Formulas used to calculate the elastic moduli from Young's modulus (E) and Bulk modulus (K) (After Birch, 1961)

Elastic moduli	Used formula	Elastic moduli	Used formula
Young's modulus (E)	$E = 2\mu(1 + \sigma)$	Bulk modulus (K)	$K = \frac{E}{3(1 - 2\sigma)}$
Shear modulus (μ)	$\mu = \frac{3K \cdot E}{9K - E}$	Poisson's Ratio (σ)	$\sigma = \frac{3K - E}{6K}$

4. Results and Discussion

4.1. Boreholes Lithological Correlation

A lithological correlation between the four boreholes logs located inside the university campus (Fig. 4): Faculty of Engineering (E), Faculty of Nursing (N), Olympic swimming pool (P) and Student activities complex (A), has been made and presented in Fig. 5. It was found that the topsoil can be described as clayey silty sand at 2 m depth, the soil mixed with gravel of limestone and chert and at the 5 m below surface the soil mixed with chalky marl and gravel of chert and limestone (AABU, 2018). Generally, the compaction degree of soil increases with depth.

4.2. Seismic Interpretation

Nine seismic profiles (MASW and SRT survey) have been conducted in this study. Fig. 4 shows the location of seismic measurements. Table (4) summarizes the layering parameters of seismic measurements: number of layers, their primary velocities (V_p), shear velocities (V_s), thicknesses and profiles orientation. Fig. 6 shows the SRT and MASW sections of seismic profile-1 and seismic profile-2. Fig. 6a shows a good correlation between the lithological units (EN-Log) and the P-velocity section. Two subsurface layers were identified by the MASW section (Fig. 6b). Fig. 6c shows SRT section of P-velocity distribution for seismic profile-2. It shows a good correlation between the lithological units (IT-Log) information and seismic section. The SRT and MASW sections show three subsurface layers

(Figs. 6c and 6d respectively). Figs 7a and 7b show the SRT and MASW sections respectively for seismic profile-3. The results were correlated with P-Log. The results show a good correlation between the subsurface geological layers and primary velocity distribution (Fig.7a). MASW section shows almost one layer with slight shear velocity range (290–300) m/s (Fig. 7b). Figs. 7c and 7d shows the SRT and MASW sections for seismic profile-4. SRT shows three subsurface layers (Figure7c), whereas, the MASW section shows almost one subsurface layer with shear velocity in the range (350-450) m/s (Fig. 7d).

Fig. 4. Location of seismic measurements (MASW and SRT), soil sampling sites and the boreholes lithological correlation in the study area

Fig. 5. Detailed lithological description of shallow top soil as correlated between the borehole logs that have been drilled for engineering constructions inside the university (AABU Archive, 2018)

Figs. 8a and 8b show the SRT and MASW sections of seismic profile-5 respectively. The results were correlated with A-Log and displayed a good correlation with the lithological unit and velocity distributions. SRT and MASW sections have large lateral variations of seismic velocity (Figs. 8a and 8b respectively) this properly due to lithological variations and/ or due to a possible structural fault. Figs. 8c and 8d show SRT and MASW for seismic profile-6, respectively. The results show three velocity layers. SRT section shows lateral variations of primary seismic velocity (V_p) in the range values (400-1800) m/sec (Fig. 8c). Figs. 9a and 9b show SRT and MASW section of seismic profile-7 respectively. The results show three seismic layers. SRT section has primary velocity in the range (255-1400) m/s (Figure 9a), while MASW section has a narrow range of shear velocity (200-600) m/s (Figure 9b).

Table 4. The results of nine seismic measurement taken in the study area

Seismic Profile	Layers	SRT (Vp)	Thickness	MASW (Vs)	Thickness	Orientation
Units		m/s	M	m/s	m	
Seismic Profile-1	Layer One	180-360	1	390	2	NE-SW
	Layer Two	360-700	3	340	6	
	Layer Three	743-750	6	390	2	
Seismic Profile-2	Layer One	150-260	0.5	250-260	4	NE-SW
	Layer Two	330-370	1.5	260-280	4	
	Layer Three	500-600	7.5	300-320	2	
Seismic Profile-3	Layer One	305-350	1	300-330	2	SW-NE
	Layer Two	490-600	6	300-350	4	
	Layer Three	620-640	3	300-380	4	
Seismic Profile-4	Layer One	340-425	1.5	350-450	Whole section	NW-SE
	Layer Two	600-740	2.5			
	Layer Three	760-860	6			
Seismic Profile-5	Layer One	500-670	4	280-300	5-0	NE-SW
	Layer Two	700-870	9-3	340-400	10-7	
	Layer Three	900-1000	2-8	410-440	0-8	
Seismic Profile-6	Layer One	400-650	10.5-7.5	230-300	5	NW-SE
	Layer Two	700-900	2-7	330-530	6	
	Layer Three	1000-1800	2.5-0.5	550-610	4	
Seismic Profile-7	Layer One	250-560	5	200-360	4	SW-NE
	Layer Two	630-1000	5	400-580	11-7	
	Layer Three	1300-1500	5	600-630	0-4	
Seismic Profile-8	Layer One	700-850	9-7	520	0-4	SE-NW
	Layer Two	920-1200	2.5-3	320-390	15-0	
	Layer Three	1400-1800	3.5-5	450-500	0-11	
Seismic Profile-9	Layer One	440-580	4-0	200-310	4	NW-SE
	Layer Two	610-780	3.5-1.5	400-520	11	
	Layer Three	800-900	7.5-13.5			

Figs. 10a and 10b show the SRT and MASW section of seismic profile-8 respectively. The results show three seismic layers. Primary velocity (V_p) is ranging from 700m/sec to 1800m/sec (Fig. 10a). MASW section has large lateral variations of shear seismic velocity this properly due to lithological variations and/ or due to a possible structural fault (Fig. 10b).

Figs. 10c and 10d show SRT and MASW sections for seismic profile-9. SRT section has a lateral variation of primary velocity in the range (440–900) m/sec (Fig. 10c). Whereas MASW section shows two seismic layers with velocity ranges between 200 and 520 m/sec (Fig. 10d).

4.2.1. Geotechnical results deduced from seismic and lab testing

In this study, the seismic methods were used for shallow subsurface characterization and to estimate the different elastic properties of superficial deposits. Based on the modeling results of seismic velocities (V_p and V_s) and using appropriate equations (Table 1), the elastic moduli for the shallow subsurface soil layer were calculated. The results are listed in Table 5.

Fig. 6. (a) 2-D Primary wave velocity section for seismic profile-1; (b) 2-D Shear wave velocity section for seismic profile-1; (c) 2-D Primary wave velocity section for seismic profile-2; (d) 2-D Shear wave velocity section for seismic profile-2

Fig. 7. (a) 2-D Primary wave velocity section for seismic profile-3; (b) 2-D Shear wave velocity section for seismic profile-3; (c) 2-D Primary wave velocity section for seismic profile-4; (d) 2-D Shear wave velocity section for seismic profile-4

Fig. 8. (a) 2-D Primary wave velocity section for seismic profile-5; (b) 2-D Shear wave velocity section for seismic profile-5; (c) 2-D Primary wave velocity section for seismic profile-6; (d) 2-D Shear wave velocity section for seismic profile-6

Fig. 9. (a) 2-D Primary wave velocity section for seismic profile-5; (b) 2-D Shear wave velocity section for seismic profile-5

Moreover, the elastic moduli (K and E) were measured at Royal Scientific Society (RSS) for samples A and B and the results are presented in Table 6. They are also used to calculate the following elastic constants (Poisson's ratio (σ), Lamé's Constant (λ) and Shear modulus (μ)) using the relationships listed in Table (3). For results verification, a comparison has been made between the elastic constants computed from seismic velocities (Samples 1 and 4) and those computed from K and E measured in RSS lab tests (Samples A and B). Fig. 11 shows a comparison between the geotechnical properties calculated from seismic velocities of MASW measurements with those measured in RSS laboratories. It was found that the Poisson's ratios (σ) measured at RSS laboratories are higher than those calculated by MASW measurements, but both of them indicate to soft, loose unconsolidated soil material types shown as Fig. 11c. On the contrary, the shear modulus (μ), Bulk modulus (K) and Lamé's Constant (λ) calculated from seismic velocities MASW measurements were found to be higher than those measured in RSS laboratories shown as Figs. 11b, 11d and 11e respectively. Fig. 11a shows a Young's modulus (E) calculated from MASW measurements were highly correlated with those measured in RSS laboratories. The small changes between the measured and calculated elastic properties can be ascribed to different reasons such as, the used formulas to calculate the geotechnical properties assumed isotropic, homogeneous subsurface which is not the case.

Fig. 10. (a) 2-D Primary wave velocity section for seismic profile-8; (b) 2-D Shear wave velocity section for seismic profile-8; (c) 2-D Primary wave velocity section for seismic profile-9; (d) 2-D Shear wave velocity section for seismic profile-9

4.3. Elastic Moduli and Geotechnical Engineering Parameters

A spatial contouring map for the different geotechnical parameter has been made and the results are presented in Figs. 12, 13, and 14. Fig. 12a shows a spatial contour map for Shear Modulus (μ). It is varying from 0.0016Gpa at NE and SW parts to 0.00037Gpa in the NW and SE parts of the study area. The Bulk Modulus (K) is ranging between 0.25 and 0.75 Gpa (Figure 12b).

Fig. 12c shows a Poisson's ratio (σ) contouring map. It shows that the Poisson's ratio is varying from 0.22 in the northeastern and southern parts of the study area to 0.34 in the south eastern and northwestern parts of the study area. Fig. 12d shows a spatial contouring map for Young's modulus (E). It shows that Young's modulus ranges from 0.001 to 0.0009Gpa. The young's modulus values increase in NW and SE parts of the study area and decreases in NE and SW parts. The study area can be classified into three zones according the K values, they area, the highest values located in the NW part, the lowest values located in the NE part and the intermediate values zone located in the southern part of the study area. Lamé' Constant (λ) ranges from 0.07Gpa to 0.49 Gpa. The lowest value is located in the northeastern part and the highest value is located in the northwestern part of the study area (Fig.13a). The calculated allowable bearing capacity (Q_a) values range from 0.5 kg/cm² to 2 kg/cm² (Fig.13b). The calculated Ultimate bearing capacity (Q_{ult}) values range from 1 kg/cm² to 4 kg/cm² (Fig. 13c). The highest values of bearing capacity are shown in the NW part of the study area. Fig.13d shows a spatial contouring map for N-value. It shows that the N-value is ranging from 40 at NE and SW part to 160 in the NW part of the study area.

Fig. 12. Spatial contour maps of the elastic moduli and geotechnical engineering parameters for the depth 2m to 3m of subsurface layers. (a) Shear modulus; (b) Bulk modulus ;(c) Poisson's ratio; (d) Young's modulus

Fig. 13. Spatial contour maps of the elastic moduli and geotechnical engineering parameters for the depth 2m to 3m of subsurface layers. (a) Lamé' Constant; (b) allowable bearing capacity; (c) Ultimate bearing capacity; (d) N-value

Fig. 14a shows stress ratios (S_i) contouring map. The stress ratio ranges from 0.25 to 0.61. The smallest stress ratio (S_i) values were found at the northwestern parts of the study area, while the largest values were found at the southeastern part of the study area indicating that, this area includes less competent materials than the rest parts of the study area. Fig. 14c shows the concentration index (C_i) contouring map. It ranges from 4.5 to 6.5. The highest value was found in the NW part of the study area. Fig. 14d shows the spatial contouring map of material index (M_i). It shows that the material index (M_i) is varying from -0.4 at NE and S parts to 0.2 in the SE and NW parts of the study area. The higher the material index values are indicating to higher competent materials.

5. Conclusions

The seismic results permitted the characterization of subsurface geology for a depth of only 10 m below ground surface. The SRT method helped in defining three subsurface zones based on the inversion of seismic P-wave velocity. The P-wave refraction velocities were found to range from 180 to 2300 m/s for the three identified layers indicating superficial soil deposits with increasing degree of compaction with depth. The S-wave velocities were found to lie in a slight velocity range from 250 to 600 m/s that poorly resolved the subsurface layering. The seismic velocities deduced from SRT and MASW measurements were used to estimate the elastic moduli and geotechnical properties of the shallow superficial deposits. As comparing the geotechnical properties calculated from seismic velocities with those measured in RSS laboratories, it was found that the Poisson's ratio (σ) measured at RSS laboratories are higher than those calculated from seismic measurements, but both of them indicate a soft, loose unconsolidated soil material types. On the contrary, the shear modulus (μ), Bulk modulus (K) and Lamé' Constant (λ) calculated from seismic velocities measurements were found to be higher than those measured in RSS laboratories. In addition, the collected soil samples for geotechnical testing were in a friable, disturbed and non-cohesive state.

The integration among seismic techniques (MASW and SRT) was proved to be an efficient means to describe near the surface and superficial soil deposits. In other words, these techniques were useful to identify the soil layer and detect the soil compaction degree. In addition, the seismic methods were also effective tools to estimate the different dynamic elastic properties of the soil layer that can be used for future engineering construction.

Acknowledgements

We gratefully acknowledge the Al al-Bayt University and Hashemite University, for providing the seismic instrumentation. The authors appreciate very much Mr. Jafar Abu Rajab and Mr. Adnan Rezaq for assistance in the seismic field surveys. The authors are very grateful to the Editor in Chief Prof. Dr. Salih M. Awadh, the Secretary of Journal Mr. Samir R. Hijab. and the Technical Editors for their great efforts and valuable comments.
